SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

(Continued from #20)

The three study projections, in conjunction with other analytical tools and system information, will be used to evaluate specific waterway improvements to meet short and long-term navigation needs. The output from these studies will serve as input to Corps' Inland Navigation Simulation Models to help analyze the performance and opportunities for improvement of the Ohio River Basin Navigation System. These data will be used in current studies relating to improvement of Gallipolis Locks, the Monongahela River, the Upper Ohio River, the Kanawha River, the Lower Ohio River, the Cumberland River and the Tennessee River, as well as other improvements.

This report and the 1975-1990 projected traffic demands discussed in it were developed by correlating the historic waterborne commodity flows on the Ohio River Navigation System with various indicators of regional and national demands for the commodities. The demand variable(s) which appeared to best describe the historic traffic pattern for each of the commodity groups was selected for projection purposes. The historic and projected values for the demand variables are based upon the 1972 OBERS Series E Projections of National and Regional Economic Activity. The OBERS projections were developed by the Bureau of Economic Analysis of the U.S. Department of Commerce in conjunction with the Economic Research Service of the Department of Agriculture.

PREFACE

This Corps of Engineers report describes one of three independent but complementary studies of future freight traffic on the Ohio River Basin Navigation System. Each of the studies considers existing waterborne commerce and develops a consistent set of projections of future traffic demands for all of the navigable waterways of the basin. Each report contains information on past and present waterborne commerce in the basin and projections by commodity group and origin-destination areas from 1975 to at least 1990.

The three projections, in conjunction with other analytical tools and system information, will be used to evaluate specific waterway improvements to meet short- and long-term navigation needs. The output from these studies will serve as input to Corps' Inland Navigation Simulation Models to help analyze the performance and opportunities for improvement of the Ohio River Basin Navigation System. These data will be used in current studies relating to improvement of Gallipolis Locks, the Monongahela River, the upper Ohio River, the Kanawha River, the lower Ohio River, the Cumberland River, and the Tennessee River, as well as other improvements.

This report, completed in January 1979, was prepared for the Corps by CONSAD Research Corporation of Pittsburgh, Pennsylvania. The study and the 1975-1990 projected traffic demands discussed in this report were developed by correlating the historic waterborne commodity flows on the Ohio River Navigation System with various indicators of regional and national demands for the commodities. The demand variable(s) which appeared to best describe the historic traffic pattern for each of the commodity groups was selected for projection purposes. The historic and projected values for the demand variables are based upon the 1972 OBERS Series E Projections of National and Regional Economic Activity. The OBERS projections were developed by the Bureau of Economic Analysis of the U. S. Department of Commerce in conjunction with the Economic Research Service of the Department of Agriculture.

A second report, completed in February 1979, was prepared for the Corps by Battelle Memorial Institute, Columbus, Ohio. The study and the 1975-1990 projections discussed in that report were developed by surveying all waterway users in the Ohio River Basin through a combined mail survey and

personal interview approach. Personal interviews were held with the major existing waterway shippers. The purpose of the shipper survey was to obtain an estimate from each individual shipper of his future commodity movements by specified origins and destinations, as well as other associated traffic information. The responses were then aggregated to yield projected traffic demands for the Ohio River Navigation System.

A third report, to be completed in September 1979 is being prepared for the Corps by Robert R. Nathan Associates, Inc. of Washington, D. C. The study and the 1975-2040 projections to be discussed in that report are much more comprehensive in scope, and focus on a much longer time frame. The basic study approach involves placing the historic production, consumption, and net shipments (by transportation mode) of commodities which move by water in the Ohio River basin into perspective with total national output. The production, consumption, and shipment estimates are being prepared for all geographic areas within the basin which are either directly or indirectly (through modal transfers) served by the Ohio River Navigation System. Economic, environmental and institutional factors which have historically affected output, consumption and modal shipments are being identified and analyzed. These same variables will then be projected through the year 2040 under alternative scenarios. Detailed waterway flow projections by commodity group and origin-destination areas will then be presented for the most probable future condition.

1.0 INTRODUCTION AND PURPOSE

In 1976 nearly 180 million tons of commerce was carried on the waters of the Ohio River navigation system. Most of this consisted of bulk-type commodities such as coal, sand, gravel, crushed rock, and petroleum fuels. These materials constitute major inputs to the basic industrial and energy production processes of the United States.

In order to insure the continued smooth flow of the above commodities, the U.S. Army Corps of Engineers must continue to maintain and improve the conditions of the rivers and navigation projects in the Ohio River Basin (ORB). Since funds for this purpose are limited, the Corps must develop a strategy for application of their financial resources so as to best achieve this goal.

As part of a systemwide study of commercial navigation in the ORB, the Huntington District of the U.S. Army Corps of Engineers has retained the services of CONSAD Research Corporation to project the demand for future ORB waterway traffic for the period 1975-1990.* The primary study area is defined to be the main stem Ohio River and all of its commercially navigable tributaries, including the Monongahela, Allegheny, Kanawha, Kentucky, Green, Cumberland and Tennessee Rivers. The elements of this analysis have consisted of the following:

TASK 1: Estimate future waterway traffic by commodity group (see Table 1 and Appendix E) for the Ohio River Navigation System for the period 1975-1990 using correlation and regression techniques. The historic waterway traffic data to be used for this task shall be collected from Waterborne Commerce of the United States, Part 2.

*This is only one of three ORB projection studies being undertaken by the Corps. The second study is based upon surveys of shippers and receivers while the third study is examining a number of basic market conditions and trends.

Table 1: COMMODITY GROUPINGS TO BE UTILIZED
FOR PROJECTING OHIO RIVER BASIN
WATERWAY TRAFFIC

COMMODITY GROUP

1. Coal and Coke
2. Petroleum Fuels
3. Crude Petroleum
4. Aggregates
5. Grains
6. Chemical and Chemical Fertilizers
7. Ores and Minerals
8. Iron Ore and Iron and Steel
9. All Other

TASK 2: Using 1969-1975 PE-PE* and BEA-BEA** flow data to be provided by the Corps of Engineers, the forecasts from Task 1 shall be allocated to the BEA economic areas and river reaches within and outside of the Ohio River Basin, by commodity group. These future movements will then be aggregated by direction to the main stem Ohio River, each navigable tributary, and through each of the seventy-one navigation projects in the Ohio River navigation system.

TASK 3: Separate, independent projections of waterway traffic by commodity group and direction of movement (upbound-downbound) will be generated for the main stem Ohio and each navigable tributary in an attempt to identify the degree of association between the behavior of the total Ohio River navigation system and its components. A similar analysis is also to be performed for traffic passing key navigation projects in the Ohio River System (see Section 2.3.3 for details). These subsystem studies are intended to test the reliability of basinwide projections throughout the system.

*PE stands for "port equivalent" and refers to a stretch of river possessing a composite of port characteristics. The term was defined as part of the Inland Navigation Systems Analysis program of the Corps of Engineers as an aid in water simulation projects.

**The term BEA as used in this report will refer to any of the 173 economic areas into which the Bureau of Economic Analysis has divided the United States.

2.0 ANALYSIS

This section describes the data, its inspection and coding, and the analytic techniques employed in projecting the demand for future ORB traffic.

2.1 Data: Collection, Coding and Manipulation Procedures

The data on the movements of commodities on the rivers under investigation were collected from Waterborne Commerce of the United States, Part 2, for the years 1953-1975. Prior to 1953, (back through 1940) this same information appeared in the Annual Report of the Chief of Engineers, Part 2, "Commercial Statistics". The former data was provided by the project sponsor, while the latter set was procured from the University of Pittsburgh library, and the libraries of the Pittsburgh and Washington, D.C., offices of the Corps of Engineers.

The data was coded much in the same way as it appeared in the later volumes of Waterborne Commerce. That is, for each commodity, the directional distinctions of up river, down river, in river, out river, and through river (up and down) were retained to provide the maximum amount of flexibility in the data file. In addition, river and year codes were also included.

Numerous inconsistencies were found in this 36-year data set. The most glaring were the many changes encountered in the commodity code classifications. Prior to 1965, when a standard 4-digit commodity classification code for shipping statistics was adopted, three different 3-digit coding schemes were encountered; one version for the years 1949-1964, another for 1948, and a third for the years 1943-1947. In addition, the data for years 1940-1942 had no codes associated with the commodity listings.

This problem was remedied by entering the 3-digit codes as they appeared into the computerized data file, and then for each 3-digit coding scheme, a computer program was written and applied to convert these codes into the standard 4-digit scheme, (see Appendix A). In the case

of the data for years 1940-1942, where no codes were utilized, the most appropriate standard 4-digit code was applied and entered into the data file.

Another inconsistency encountered was the extremely detailed breakdown of commodity tonnages in the older data compared to what was adopted in the standard 4-digit scheme. As an example, in 1940 on the Ohio River, in the "Outbound Ores, Metals, and Manufactures of" category, such commodities as grave vaults, range boilers, and signs were listed. However, in consulting the standard 4-digit code, these commodities and several others listed in that same category were all subsumed in the "Fabricated Metal Products Except Ordnance, Machinery, and Transportation Equipment" category. In general, every effort was made to locate the most appropriate standard 4-digit classification.

The Cumberland River presented a unique problem. Several years of commodity tonnage data was organized only by "Below and Including Nashville" and "Above and Excluding Nashville" categories. No separate "whole river by direction" chart existed. Special care had to be taken in converting this data breakdown to the one we were employing for all the rivers. The "net total" listing (directionless) was used as a guide in this conversion task.

The Ohio River also presented a unique situation. A separate "oceangoing" chart was often presented in addition to the domestic data. This chart included imports and exports as well as the "domestic coastwise" category which refers to domestic traffic receiving a carriage over the ocean and/or Gulf of Mexico. Whenever this chart appeared, the tons listed for a particular commodity were added to the tons for that commodity listed in the domestic chart, in the appropriate direction (e.g., imports were added to the "in" tonnages in the domestic chart).

In addition to the above data, CONSAD was provided with BEA-BEA and PE-PE movement data on all commodities for the years 1969-1976, and data on the 71 lock and dam projects by commodity group and direction as far back historically as existed. The former data set was provided on tape and the analysis of this information will be discussed in Section 2.4.1, below. The latter data set included data for the key navigation projects for which separate independent projections of future commodity group flows were to be made. In order to make these projections this data has to be coded, and in doing so, a major problem was encountered.

Although the analysis was supposed to be performed by direction (upbound-downbound), much of the annual traffic data was available only in aggregate (combined upbound-downbound). Faced with this situation, CONSAD, after consultation with the project monitor, decided to perform the projections of traffic passing key lock and dam projects in aggregate.

The three data sets discussed above along with their uses are summarized in Table 2.

2.2 Selection of Independent Variables

Assuming that the patterns of past commodity flows bear some relationship to their future flows, and also assuming that these commodities are moving in response to the economic demands of the Nation, it is believed that quantitative relationships exist between economic indicators and waterway traffic levels. It is expected that these relationships could be determined from historical data using correlation and regression techniques and that these relationships could then appropriately be applied to future economic projections to obtain projections of future demand for waterway traffic.

Ideally, any economic or other demand indicator should provide annual data for the years 1940-1975 and should also be projected for the years 1980, 1985, and 1990. However, in searching for economic indicators that could logically be considered as a driving force behind the movements of a particular commodity or commodity group on the waterways of the Ohio River Basin, it was found that except for GNP and national population, compatibility between annual historical data and the projected data was extremely rare. More specifically, we were able to locate numerous annual data series for all types of economic variables, but usually there were no projections in existence based upon the annual series. The projections that we were able to locate were not based upon historical data going as far back as 1940.

After much searching and several conversations with faculty members at Memphis State University who had been involved in a similar task for the Louisville District of the Corps of Engineers,* it was decided

*Existing and Expected Commodity Flow, Port of Louisville, Kentucky, Allen & Hoshall, Inc., Memphis, Tennessee, December 1977.

Table 2: The Three Sets of Waterway Traffic Data

<u>Data Set</u>	<u>Source</u>	<u>Description</u>	<u>Use</u>
1	<u>Waterborne Commerce of the United States</u> , Part 2 1953 - 1975 <u>Annual Report of the Chief of Engineers</u> , Part 2, "Commercial Statistics" 1940 - 1952	Annual tonnages for each river arranged by commodity and direction	Projection of 1980, 1985 and 1990 system level and individual river level commodity group tonnages.
2	U.S. Army Corps of Engineers, Huntington District	1969 - 1976 BEA-BEA and PE-PE O-D flows for each commodity	Test reliability of using basinwide projections as a means of determining future localized traffic flows.
3	U.S. Army Corps of Engineers, Huntington District	Historical lock and dam data arranged by direction and commodity group.	Test reliability of using basinwide projections as a means of determining future localized traffic flows.

that our best source would be the Bureau of Economic Analysis in the U.S. Department of Commerce. The data tapes purchased from BEA included a 37-industry breakdown of earnings, total personal income, per capita income, and population. These categories were provided on an annual basis for the years 1965-1975 and included both national and BEA level data. In addition, a somewhat less detailed data set for thirteen SMSA's on or near the rivers in the study area was also obtained.

All of the above data sources are compatible with the OBERS Projection Series* prepared by the Bureau of Economic Analysis in conjunction with the Economic Research Service in the Department of Agriculture for the U.S. Water Resources Council. In addition to the projected earnings, income, etc., for the years 1980, 1985, and 1990, this series also provides observed historical data for the years 1950, 1959, and 1962. This brings the number of available historical observations up to fourteen.

2.3 Regression Procedures

2.3.1 System

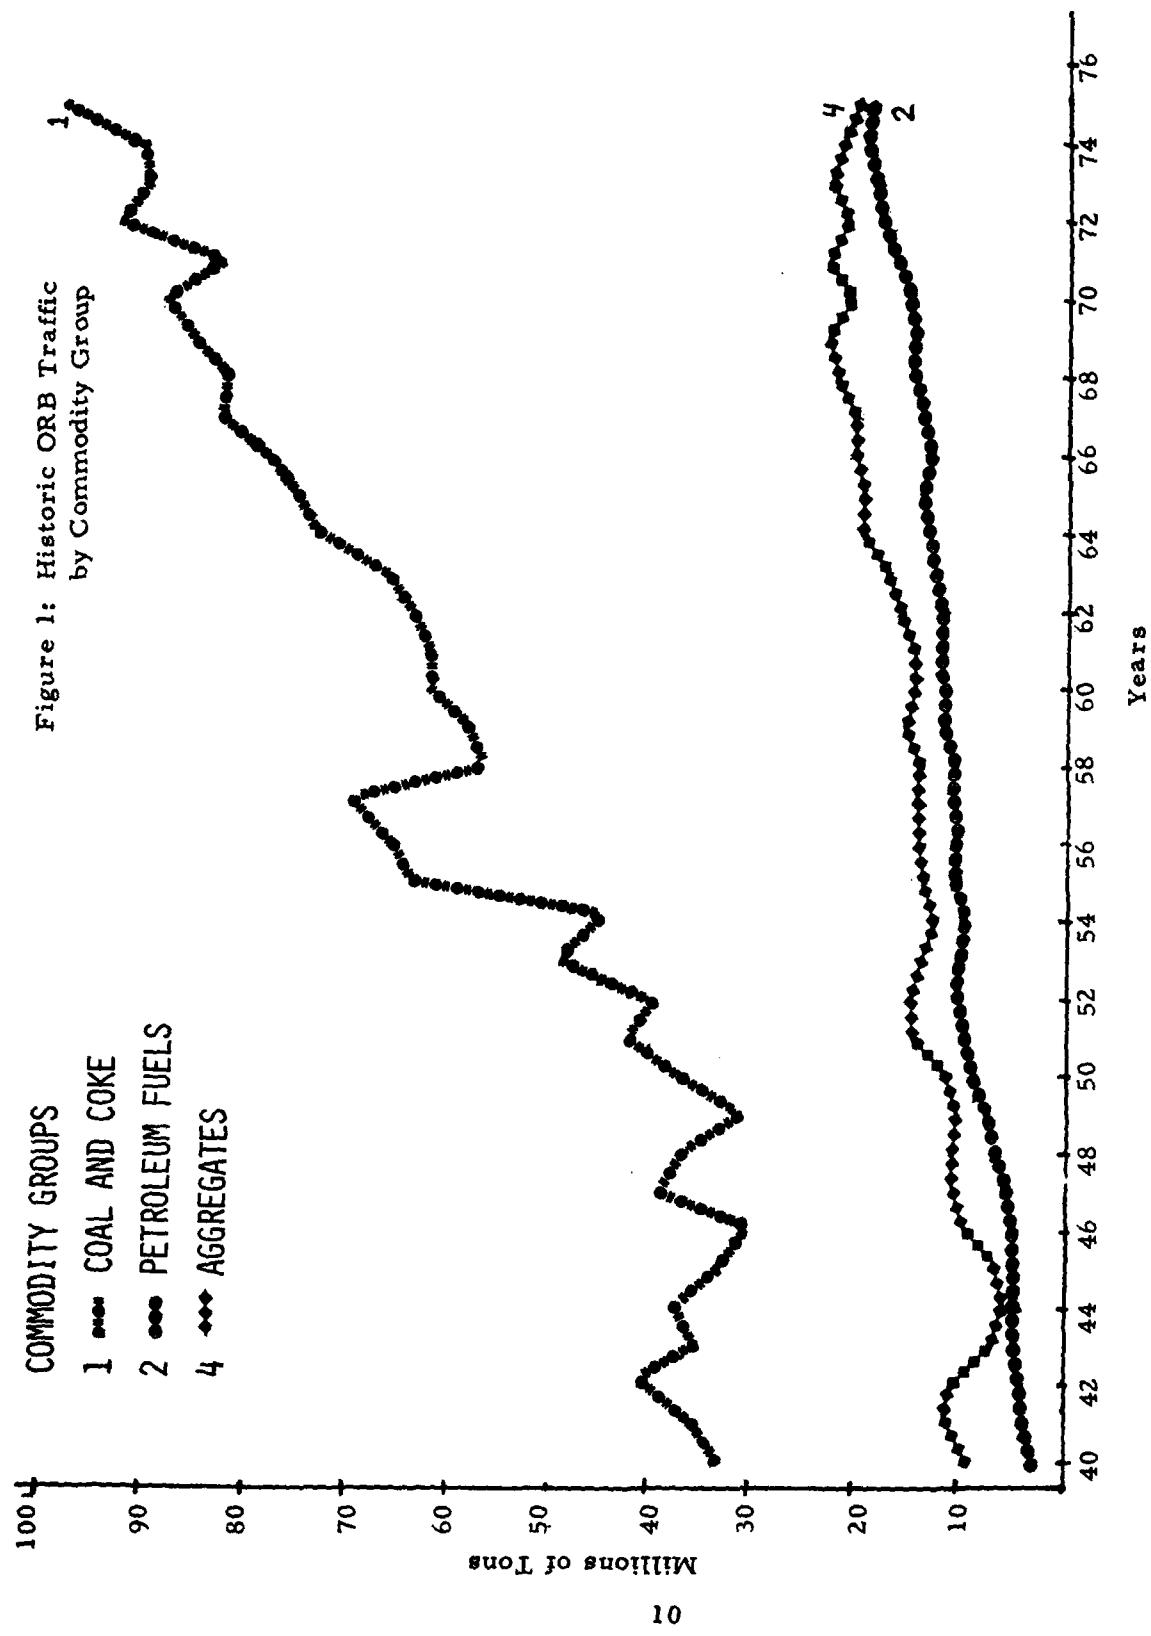

It was necessary initially to aggregate the Waterborne Commerce data set from an individual river format to a "total system" format for each of the nine commodity group categories specified by the Corps. This was accomplished by summing the tonnages for all six directions on the Ohio River together with the tonnages for the two intra-river directions (up and down) for each of the seven tributaries. In this manner all ORB traffic was aggregated without any double counting (see Table 3 and Figures 1, 2 and 3).

After aggregation, a severe drop in crude petroleum shipments for the system as a whole was discovered. This decrease was found to correspond with the opening of a pipeline used for the transport of crude

by Commodity Group

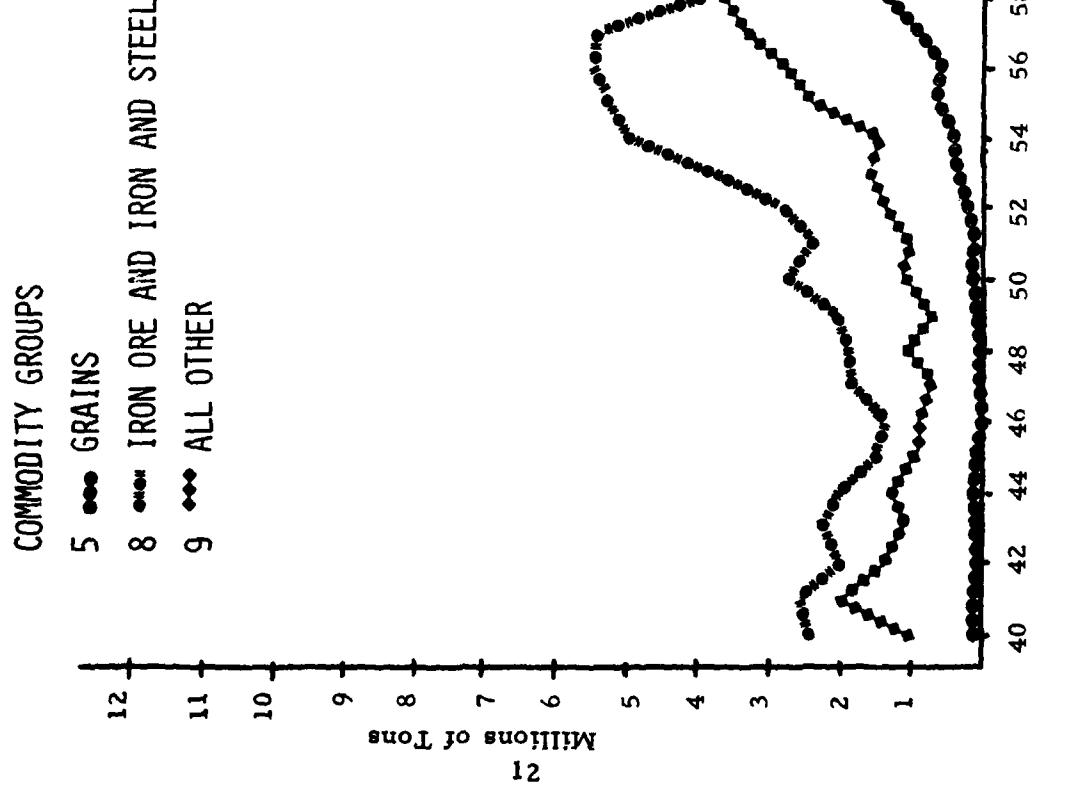

Figure 3: Historic ORB Traffic
by Commodity Group

petroleum. Regression procedures were abandoned for this commodity group in favor of other means of determining future shipments (see Section 3.1.1 for details).

The first step in the regression procedure for the other eight commodity groups was to develop a series of regression equations based on the complete set of 36 years of historical data for each of the nine commodity groups. The functional forms utilized were:

1. Straight line: $Y = a + bX$
2. Second degree curve: $Y = a + bX + cX^2$
3. Geometric curve: $Y = a \cdot X^b$
4. Exponential curve: $Y = a \cdot b^X$

In addition to a time series, regression runs were made using Gross National Product and national population as independent variables (36-year series). At this stage severe problems of multicollinearity arose. The correlations between time and GNP and time and national population were .99062 and .99772, respectively. The correlation between GNP and population was .98400. This degree of correlation eliminated the idea of using any multivariate regression equations at this level of analysis. It was decided that a simple regression using GNP as the independent variable would be the best procedure under these circumstances. The equations retained for analysis and the projected commodity group tonnages they yield appear in Section 3.1.1, Tables 7-14.

The criteria employed for retention of a regression equation were goodness of fit (R^2) and "appropriateness" of the projected tonnage. By "appropriateness" we mean whether or not the projected value seemed reasonable in light of the historic tonnage values. As an example, an equation predicting a ten-fold increase in the tonnage of grains moving on the Basin's waterways, where traffic data and transport developments would not indicate such growth, would be rejected, despite a high R^2 value.

The next group of independent variables tested were national level income and earnings figures. These variables are listed in Table 4.

**Table 4: Definition of Independent Variables
Considered in the Analysis**

	<u>National Level</u>	<u>Basin Level</u>
Gross National Product	XN01	---
Population	XN02	XB02
Total Personal Income	XN03	XB03
Per Capita Income	XN04	XB04
Total Earnings	XN05	XB05
Earnings in Agriculture	XN06	XB06
Earnings in Mining	XN07	XB07
Earnings in Coal Mining	XN08	XB08
Earnings in Manufacturing	XN09	XB09
Earnings in Manufacture of Food and Kindred Products	XN10	XB10
Earnings in Manufacture of Chemicals and Allied Products	XN11	XB11
Earnings in Petroleum Refining	XN12	XB12
Earnings in Manufacture of Primary Metals	XN13	XB13
Earnings in Manufacture of Fabricated Metals	XN14	XB14
Earnings in Transportation, Communica- tion & Utilities	XN15	XB15
Earnings in Wholesale & Retail Trade	XN16	XB16
Earnings in Contract Construction	XN17	XB17

As was noted above, this data included annual values for 1965 through 1975 plus a few prior selected years; the number of observations (data points) thus dropped to fourteen at this stage of the analysis.

Rather than allow the computer to choose among this rather long list of variables, an initial screening was undertaken. For each commodity group, in addition to the more general variables (Total Personal Income, Per Capita Income, Total Earnings) which were tested for all commodity groups, several "specifically targeted" variables were also chosen. More precisely, only those variables which possessed some identifiable economic relationship to the commodities in a particular commodity group were included in the analysis. Table 5 lists the choices of independent variables tested by commodity group.

Multicollinearity again presented a problem. Except for XN06, XN07 and XN08 only two correlation values of less than .9 were found between pairs of variables. To deal with this situation the SPSS* stepwise regression package was utilized. This package allows the user to specify a set of three statistical criteria to be used in screening variables for inclusion in the equation. These parameters are the number of variables, the minimum acceptable F-test value, and the minimum acceptable tolerance level which refers to the proportion of the variance of a variable being considered for inclusion not explained by the variables already in the regression equation.

The maximum number of variables to be allowed was chosen at three. The minimum F-test value was set high enough so that given the number of observations and variables in the equation, there was a 95 percent probability that the coefficient associated with a particular variable was significant. Finally the tolerance level was set at .01, meaning that a variable would be entered only if the proportion of its variance not explained by the other variables exceeded one percent. Results from this computer run also appear in Section 3.1.1, Tables 7-14.

A third series of independent variables tested consisted of basin level income and earnings figures. To construct these variables, data

N - National Level
B - Basin Level

*At the basin level, two separate runs were made in an attempt to include only one of the "general" variables, XB03 and XB06. The equation yielding the better fit was chosen.

from the thirteen BEA areas which cover the study area (see Figure 4) were aggregated. These variables are also listed in Table 4.

Initial inspection of these variables indicated that the multicollinearity situation was much less severe, with many of the correlations between pairs of independent variables lying in the .6 to .9 range.

At this level of analysis it was decided that the independent variables entered into the stepwise regression program would be restricted to the commodity specific variety except where the more general variables seemed particularly appropriate (e.g., basin population as a demand indicator for petroleum fuels). This decision was made in an attempt to provide the best possible direct relationship between the commodity group and the explanatory variable(s). For a complete list of the basin level variables tested, by commodity group, see Table 5. The rationales for the pairing of specific independent variables with each commodity group are provided in Table 6.

It was also decided that the restrictive minimum F-test level for variable inclusion would be somewhat eased so as to allow variables that had rather direct relationships to the commodity groups into the regression equation even if their coefficients did not quite reach the 95 percent significance level. Results from this basin level analysis are given in Section 3.1.1, Tables 7-14.

Of the nine commodity groups analyzed in this study, Commodity Group 1, Coal and Coke, has historically accounted for the most significant portion of total traffic (see Table 3). Within this group, steam coal, used to generate electricity, is by far the most important commodity (by tonnage). A "good" single indication of steam coal demands was not identified within the OBERS framework, and the industry specific variables included in the regression procedures represent secondary demand variables since these industries tend to be major energy users.

Because of the significance of steam coal to this projection study, it was felt that some additional "sensitivity" testing was called for. Under the assumption that Earnings in Transportation, Communication, and Utilities provides the best single indication of direct demand for steam coal, and also assuming that Population and Earnings in Manufacturing provide the best secondary demand indicators for non-commercial and commercial use of electricity, respectively, regression procedures were undertaken in which Earnings in Transportation,

Communication and Utilities was forced into the equation, followed by either or both of the other two variables. The projections which resulted from the equations developed in this manner were remarkably close to the projections obtained as a result of the regression procedures described earlier in this section. At both the national and basin levels, Population and Earnings in Manufacturing yielded insignificant F-test values when entered into the equation after Earnings in Transportation, Communication and Utilities. Utilizing the single independent variable equations, coal and coke tonnage was projected at $174\frac{1}{2}$ million tons (national level data) and 181 million tons (basin level data) in 1990. Comparison with the projections in Table 60 shows a 3 million ton difference at the national level and slightly over a million tons at the basin level.

These results suggest that coal and coke projections are rather insensitive to the choice of OBERS variables utilized in the regression equation. They also add a degree of confidence to the reliability of the projections.

2.3.2 Individual Rivers

The subsystem regression procedures described in this section and in the following section (2.3.3 Key Lock and Dam Projects) were undertaken primarily as a means of determining whether traffic on the system components are moving in response to the same demand variables and with similar correlations as is occurring at the system level. Since the ultimate goal of this study is to arrive at projections of demand for future lock and dam traffic, and because these projections will be determined as a result of system level analysis modified by recent subareal O-D trends, it was felt that a subsystem analysis would be of value in determining the reliability of allocating systemwide projections to the subsystems (individual rivers and lock and dam projects).

Figure 4: ORB Showing Rivers
and B.F.A. Regions

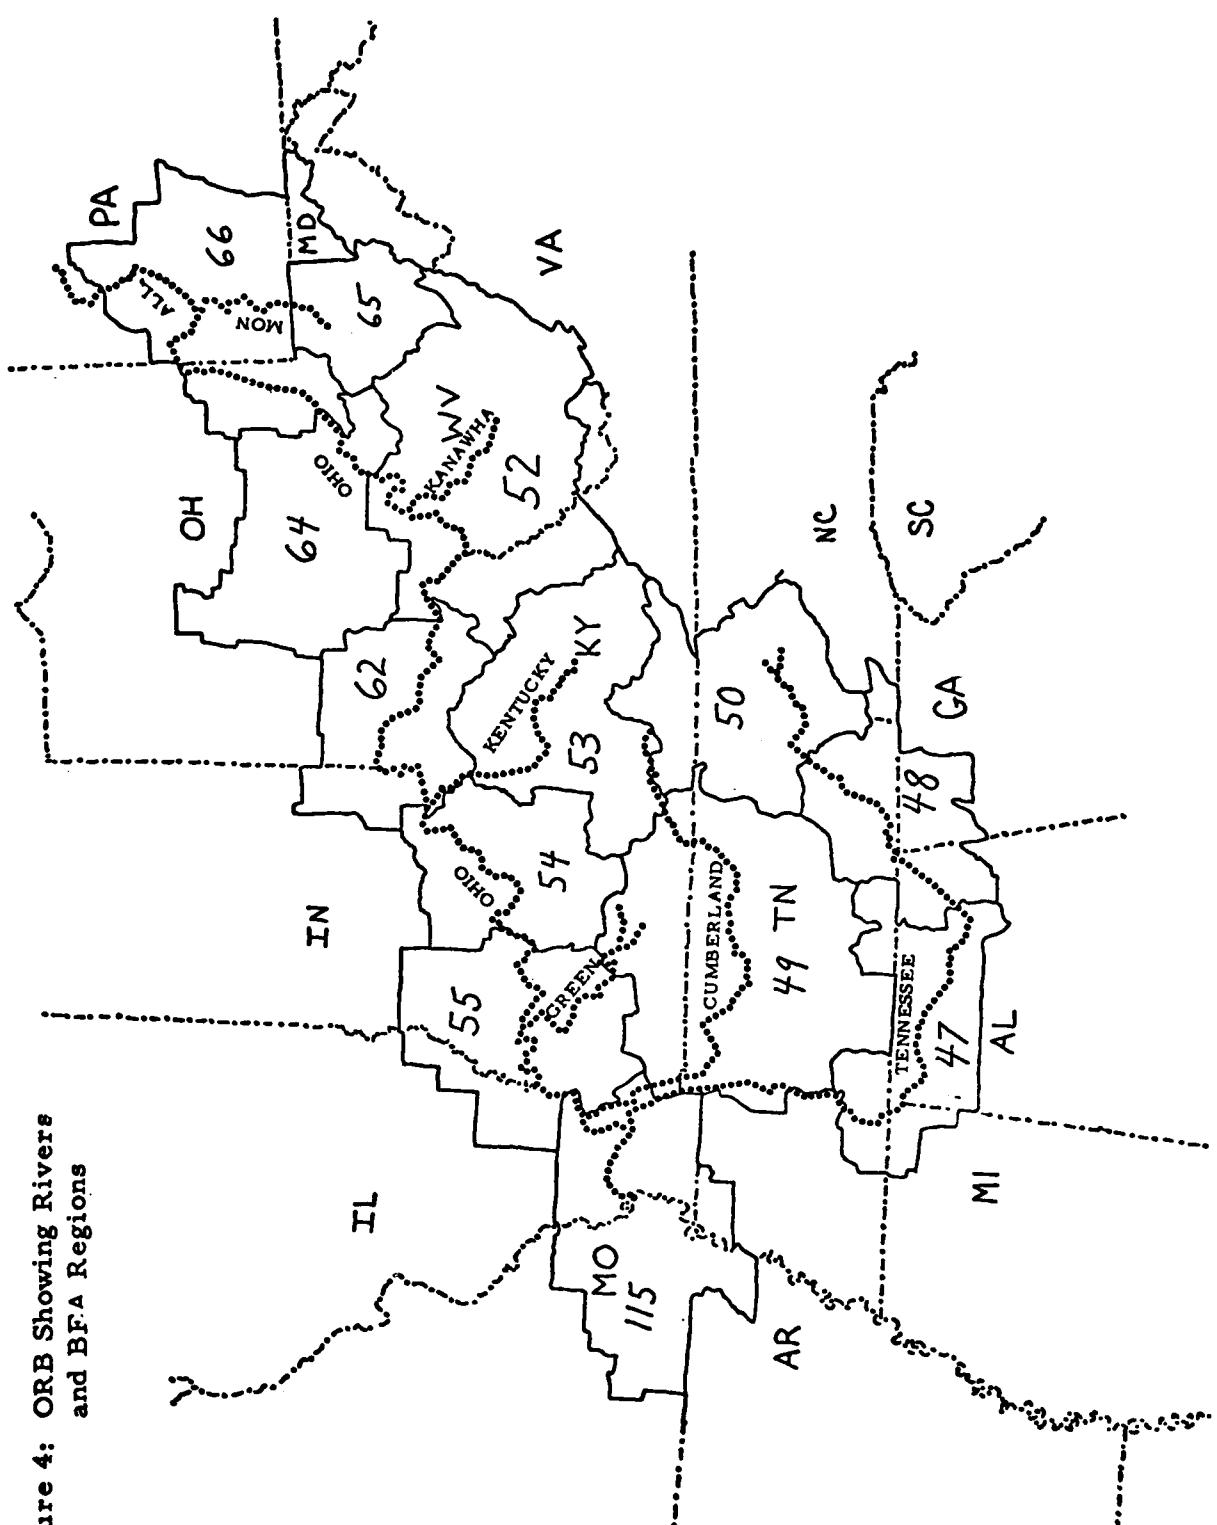

Table 6: Rationale for Pairing of Independent Variables with Commodity Groups

Dependent Variable: Traffic by Commodity Group	Independent Variable: Economic Factor Tested	Relationship Between Commodity Group and Independent Variable
1. Coal and Coke	Earnings in Coal Mining	Increase or decrease in coal mining earnings may correspond to an increase or decrease in the tonnage of coal on the waterways of the ORB
	Earnings in Transportation, Communication, and Utilities	Steam coal for generation of electricity is the primary use of the coal shipped on ORB waterways
	Earnings in the Manufacture of Chemicals and Allied Products	In addition to the electricity consumed in the manufacturing process, some of the chemicals and associated by-products have a coal base
	Earnings in the Manufacture of Primary Metals	Coal and coke are essential ingredients in the production of iron and steel
	Earnings in the Manufacture of Fabricated Metals	This represents a secondary demand variable since fabricated metals are fashioned from primary metals
	Population	Intended to provide the best general demand indicator for non-commercial use of electricity
2. Petroleum Fuels	Earnings in Manufacturing	Intended to provide the best general demand indicator for commercial use of electricity
	Population	The population of an area determines the demand for home heating fuel and gasoline for automobiles
	Earnings in Petroleum Refining	Reflects levels of activity at petroleum refineries which would relate to volume transported
	Earnings in Transportation, Communication, and Utilities	Petroleum fuels power transport vehicles and are used to generate electricity
4. Aggregates	Earnings in the Manufacture of Primary Metals	This commodity group includes limestone flux, an important ingredient in iron and steel production
	Earnings in the Manufacture of Fabricated Metals	This is a secondary demand variable since fabricated metals are fashioned from primary metals
	Earnings in Contract Construction	Building stone, sand, gravel, and crushed rock are used in construction work
5. Grains	Earnings in Agriculture	Tonnage of grains moving on ORB waterways may correspond to agricultural earnings
	Earnings in the Manufacture of Food and Kindred Products	Grains are milled and used in many types of foods
	Earnings in Wholesale and Retail Trade	Sales of grains, meat (grain-fed animals), and numerous soybean products relate to the demand for grains
6. Chemicals and Chemical Fertilizers	Earnings in Agriculture	Agriculture industry consumes a great deal of chemical fertilizers and pesticides
	Earnings in Manufacturing	Dyes, plastics, synthetic rubber and fiber paints, and other chemicals are consumed in various manufacturing processes
	Earnings in the Manufacture of Chemicals and Allied Products	Earnings by these industries should relate to the tonnage of chemicals and fertilizers on ORB waterways

Table 6 (continued)

Dependent Variable: Traffic by Commodity Group	Independent Variable: Economic Factor Tested	Relationship Between Commodity Group and Independent Variable
7. Ores and Minerals	Earnings in Mining	Levels of earnings of the mining of various ores and minerals should correspond to levels in the tonnage of ores and minerals on ORB waterways
	Earnings in Manufacturing	Nonferrous metal ores, salt, sulfur, and gypsum are used in the manufacture of a variety of goods
	Earnings in the Manufacture of Primary Metals	Copper, bauxite, manganese, and other nonferrous metal ores are used in the manufacture of various primary and fabricated metals
	Earnings in the Manufacture of Fabricated Metals	
8. Iron Ore and Iron and Steel	Earnings in Mining	Earnings in the mining of coal, iron ore, and limestone may relate to the tonnage of iron ore and iron and steel on ORB waterways
	Earnings in Coal Mining	
	Earnings in the Manufacture of Primary Metals	Earnings in iron and steel industries may relate to the tonnage of this commodity group on ORB waterways
	Earnings in the Manufacture of Fabricated Metals	A secondary demand variable since iron and steel are fashioned into numerous fabricated metal products
	Earnings in Contract Construction	Many steel products (girders, concrete reinforcing rods, pipes, etc.) are used by the construction industry
9. All Other	Total Personal Income Total Earnings Earnings in Manufacturing Earnings in Wholesale and Retail Trade	This commodity group is made up of all commodities that were not listed in the other groups, and therefore covers a wide variety of goods. Total personal income is intended to provide a demand index to the amount of money people have available for consumption of essential and non-essential goods. Total earnings should relate to the overall demand for raw materials and semi-finished goods by the industrial sector. Earnings in manufacturing and wholesale and retail trade are somewhat more specific in that they relate to the demand for the inputs to the many manufacturing processes and goods for sale, respectively.

* A small portion of the ORB petroleum fuels are used in both manufacturing and energy production processes. However, this was judged not to be a significant demand indicator.

At the individual river level, the analysis was to be performed by direction (upstream-downstream) and commodity group. Given the format used in coding the data, it was quite simple to aggregate the data into upstream and downstream categories for the seven tributaries under study. For the Monongahela, Allegheny, Kanawha, Kentucky, and Green Rivers, the upstream category was created by summing the "up" and "in" river categories, while the downstream category consisted of the sum of the "down" and "out" categories. For the Cumberland and Tennessee Rivers, the upstream category consisted of the sum of "up, in" and "up-through" categories, and the downstream category consisted of the sum of "down, out" and "down-through" categories.

Matters were not quite as simple in the case of the mainstream Ohio River. "In-river" and "out-river" do not specify a direction on the Ohio since commodities can enter or leave the Ohio either at the mouth (Mississippi River) or at any one of the tributaries. Therefore, it was decided that a third directionless category (titled "other") would be created consisting of the sum of "in-river" and "out-river" traffic. The "upstream-downstream" categories were also retained, but in this case consisted of "up" plus "up-through" and "down" plus "down-through" categories, respectively.

The data aggregations described above appear in Appendix B.

In an attempt to identify the degree of association between the behavior of the total Ohio River navigation system and its components, the same independent-dependent variable relationships tested at the system level* were also tested at the individual river level for each commodity group and river, by direction (see Table 5).

At this level of analysis only linear regression procedures were undertaken using the SPSS stepwise regression package described in the previous section of this report. The decision to eliminate the other functional forms was based on the fact that CONSAD had already decided to use

*No analysis utilizing the national level income and earnings data (fourteen years) was undertaken.

the linear regression equations to project future commodity group tonnages at the system level. Since this subsystem component analysis was intended primarily as a check of the relationship of the system as a whole to the system components, we saw no reason to continue with the nonlinear forms of analysis.

In an attempt to determine whether traffic on the individual rivers was moving in response to more localized variables, additional regression procedures were undertaken. For the Allegheny and Monongahela Rivers, independent variables based solely on BEA 66 were used. For the Kanawha River, BEA 52 variables were tested. These river-BEA relationships are geographical in nature, i.e., the Allegheny and Monongahela Rivers are located mostly within BEA 66 and the Kanawha River is located in BEA 52 (see Figure 4). The same commodity group - industry earnings relationships utilized at the basin level were retained at the BEA level. Both the basin level and BEA level independent variable regression results appear in Section 3.1.2.

2.3.3 Key Lock and Dam Projects

Of the 71 navigation projects in the ORB there were ten projects (three on the Ohio River, one each on the seven tributaries) that were chosen by the Corps of Engineers for analysis in this study (see Table 37 for listing). For these ten projects, separate, independent projections of future traffic were to be made for the three major commodity groups transiting each project. Examination of the historic data provided by the Corps showed the two of the projects only handled a single commodity group, and in several cases it was difficult to distinguish the "top three", based on the historic tonnages. The final commodity groups chosen for analysis for each project also appear in Table 37.

The data was provided by commodity group and direction, but, as was mentioned earlier, the directional distinction was not always preserved and the projections had to be done in aggregate, rather than by direction. The projection procedures employed for these lock and dam projects were similar to those utilized for the individual river projections.

Again, equations obtained using basin level independent variables were tested first. The same commodity group specific independent-dependent variable relationships tested at the system and individual river level were also used for the key lock and dam project demand regressions.

In an attempt to determine whether traffic passing through the key lock and dam projects was moving in response to more localized variables, additional regression procedures were undertaken. Specifically L&D #2 on the Allegheny River and L&D #7 on the Monongahela River were tested against BEA 66 variables, and the Winfield L&D on the Kanawha River was tested against BEA 52 variables. Both the basin level and BEA level independent variable regression results appear in Section 3.1.3.

2.4 Origin-Destination Movements

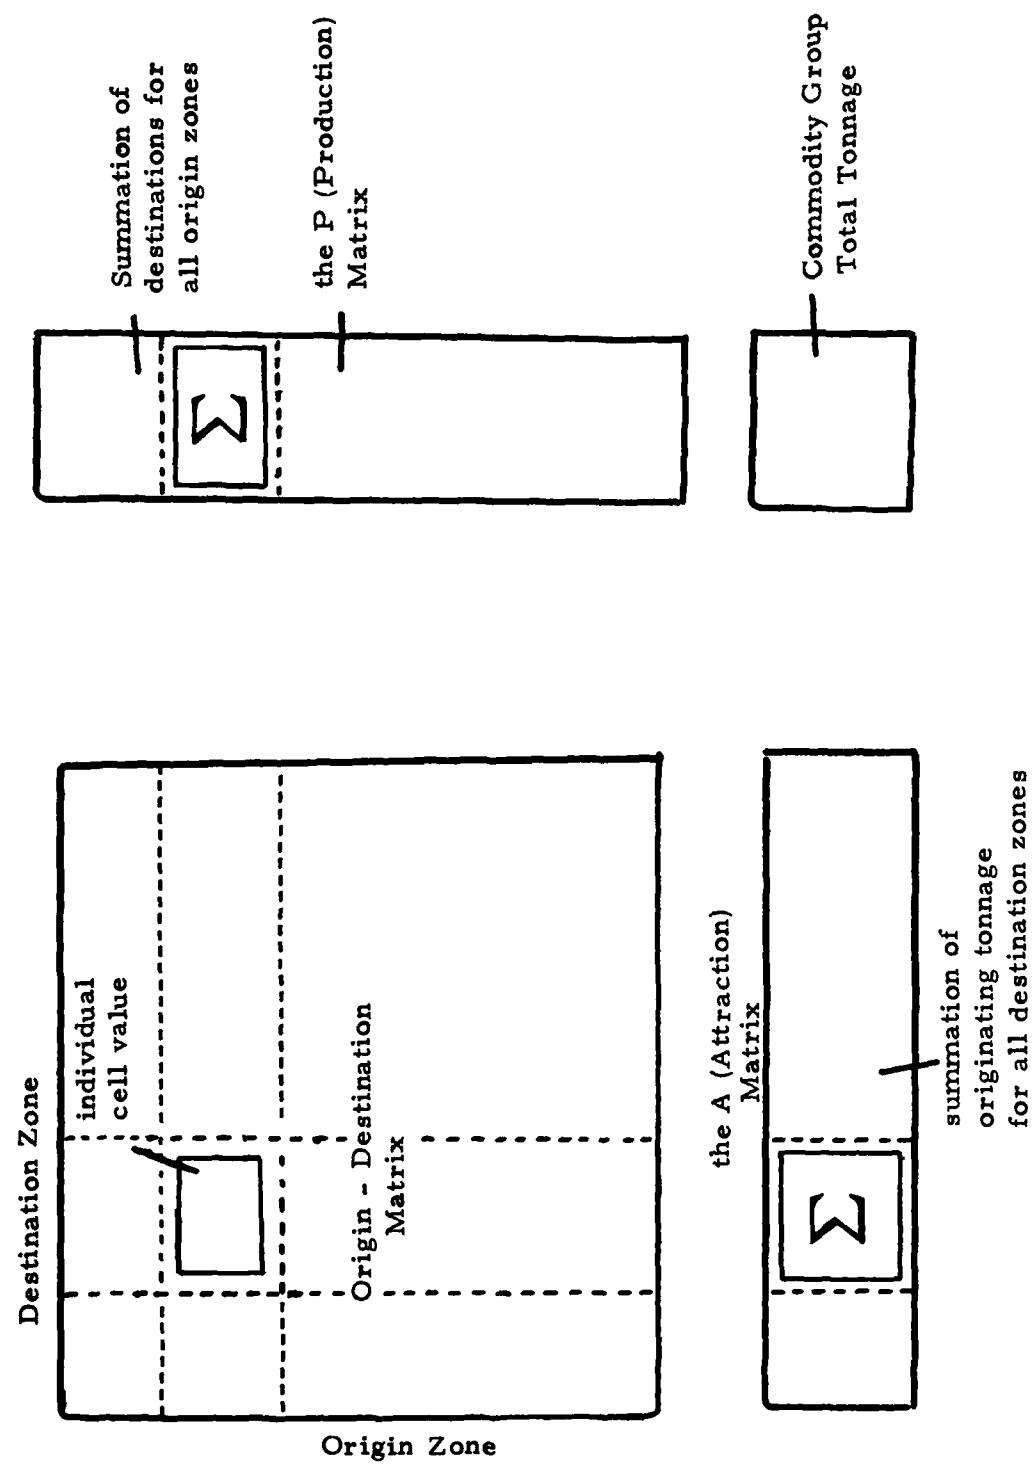

2.4.1 Preliminary Examination of O-D Movements

Given eight years of O-D movement data by commodity, both at the BEA and PE level, it was decided that a preliminary data inspection was called for prior to undertaking any analysis. Therefore, a computer printout was obtained such that for each commodity group and year, two matrices were constructed. The first was arranged so that for each origin BEA a complete list of destinations was printed along with the associated tonnages and the percent of the total shipped from that BEA represented by that tonnage. In addition, the total tonnage shipped from each BEA and the percent of total commodity group tons for the basin represented by that tonnage also appeared. The second matrix was arranged similarly, but for destination BEA's. In all cases eight years worth of data were examined so as to observe trends.

From the above printout two types of tables were assembled, representing two levels of analysis. For clarification on these two types of tables the reader is referred to Figure 5, which shows the components of an origin-destination matrix and several related vectors. The first type of table essentially displays the P and A (Production and Attraction) Matrices, over time, for each commodity group. This shows the relative importance of each zone (BEA Region) within the Basin and how this has varied with time.

The second type of table, displays the distribution of the individual cell values for each element of the P and A matrix, and how that has varied in time. This table shows shifts in movements beyond those which occur due to differences in production and attraction rates over time.

Figure 5: Schematic of Relationships in an
Origin - Destination Matrix

At the more aggregated level, (the P and A Matrices) for each commodity group, a list of origin BEA's, the tonnages shipped from each, and the percent of total commodity group tons represented by that tonnage for each of the eight years between 1969 and 1976 (inclusive) is displayed. At the top of the table, for each year, a percent, representing what part of the total tons of a particular commodity group originated in the ORB also appeared. Similar tables were constructed for destination BEA's.

Next, for commodity groups 1, 2 and 4, historically representing between 75 and 80 percent of all Basin traffic, an analysis of the destinations of major shipping BEA's and the originations of receiving BEA's was undertaken, and the second type of table was also constructed. More specifically, for each origin BEA shipping a substantial tonnage of a commodity group, the top five destinations, tonnage destined for each, and percent of total originating tonnage represented by that destined tonnage over the eight year period were listed. A similar representation is provided for destination BEA's.

All tables described above appear in Appendix D; the first type of table carries the designation "P/A", while the second type is designated by "O/D". It is important to note the connection between each series of tables. The total tonnage figure appearing in the bottom row of the latter series of tables described above is equal to the tonnage figure appearing in the former series of tables in the corresponding year and BEA position.

In order to further clarify the preceding discussion, two tables (one of each type) from Appendix D appear on the following pages. The first table displays the annual tonnage of Commodity Group 1 shipped from each BEA between 1969 and 1976. Immediately below each tonnage a number appears which represents the percent of all Commodity Group 1 shipments involving the ORB that were shipped from that particular BEA.

The second table provides a breakdown of the BEA 66 shipments (first row of first table), answering the question "What were the destinations of the BEA 66 coal and coke over time?" The destination BEA as well as the number of tons and the percent that the tonnage represents compared to the total shipped from that BEA are included.

For instance, in 1972 BEA 66 shipped 28,579,605 tons of coal and coke (first table, first line). This represents 30.35 percent of all coal

and coke shipments involving the ORB in 1972. Referring to the second table, one can determine that 85.26 percent or 24,368,288 tons remained in BEA 66, 8.08 percent or 2,308,212 tons went to BEA 62, and so on. In this manner one can follow the O-D patterns through time at the BEA level for Commodity Groups 1, 2 and 4.

2.4.2 Obtaining Future O-D Movements: Shift-Share Analysis and the Fratar Method

After examination of the eight years of O-D movement data, it was decided that the most appropriate technique for extrapolating the historic O-D movement trends to 1980, 1985 and 1990 O-D flows was to utilize Shift-Share analysis in conjunction with the Fratar Growth-Factor method. This decision was made in light of the overall stability in the patterns of O-D movements (see Appendix D). Both of these techniques are well suited for extrapolation purposes when no severe changes in historic patterns are anticipated.

Shift-Share analysis,* given historic movement patterns and projections of future commodity group activity (see Section 3.1.1), develops future shipping and receiving (O and D) totals for each commodity group and subarea (BEA or PE). These totals correspond to row and column sums of a commodity-specific O-D matrix. The Fratar technique** will then construct the future matrix cell entries according to a base year pattern adjusted by subareal growth factors.

More specifically, the Shift-Share methodology acts recursively on a series of commodity group specific O-D matrices. Each subarea is examined in light of the total originating shipments (row sum of O-D matrix) and total destinations (column sum). Shift-Share analysis interprets subareal growth as dependent upon two "parent forces": growth in total

*Dunn, E.S., Jr., "A Statistical and Analytical Technique for Regional Analysis", *Papers, Regional Science Association*, 6(1960), 97-112.

**Hutchinson, B.G., Principles of Urban Transport Systems Planning, Washington, D.C.: Scripta Book Company, 1974, pp. 84-85.

shipments and growth in the commodity group shipments between successive time periods. Any growth inconsistent with those parent forces is attributed to unique subareal characteristics.

At this point in the discussion it becomes convenient to introduce mathematical notation to facilitate the description of the Shift-Share methodology. We define the following:

$$Q_{ij}^{gt} = \text{total annual tonnage of commodity group } g \text{ originating from subarea } i \text{ and terminating at subarea } j \text{ in year } t \text{ (O-D matrix cell entry).}$$

$$O_i^{gt} = \sum_{j=1}^n Q_{ij}^{gt} = \text{total annual tonnage of commodity group } g \text{ originating from subarea } i \text{ in year } t \text{ (row sum of O-D matrix: the P matrix).}$$

$$D_j^{gt} = \sum_{i=1}^m Q_{ij}^{gt} = \text{total annual tonnage of commodity group } g \text{ terminating in subarea } j \text{ in year } t \text{ (column sum of O-D matrix: the A matrix).}$$

$$Q^{gt} = \sum_{i=1}^m O_i^{gt} = \sum_{j=1}^n D_j^{gt} = \sum_{i=1}^m \sum_{j=1}^n Q_{ij}^{gt} \\ = \text{total annual tonnage for commodity group } g.$$

$$Q^t = \sum_{g=1}^9 Q^{gt} = \text{total annual tonnage in year } t.$$

Then between successive years the incremental growth in shipments* for commodity group g in subarea i (ΔO_i^{gt}) is seen by shift-share as being comprised of the following three components:

*A similar analysis is performed for the D_j^{gt} 's.

$$\Delta O_i^{gt} = R_i^{gt} + S_i^{gt} + U_i^{gt}$$

where R_i^{gt} = raw increment which would occur if commodity group g in subarea i were to behave as the aggregate regional growth rate for all commodity groups.

S_i^{gt} = any growth (or decline) in commodity group g over and above the regionwide aggregate growth.

U_i^{gt} = the "unique" component: any growth (or decline) in commodity group g within subarea i for which the first two components (R_i^{gt} , S_i^{gt}) take no account.

These components are calculated in the following manner:

$$R^{gt} = r^t O^{g(t-1)} \text{ where } r^t = \frac{Q^t - Q^{t-1}}{Q^{t-1}}, \text{ the basinwide growth rate for all commodities.}$$

$$S_i^{gt} = (y^{gt} - r^t) O_i^{g(t-1)}$$

where $y^{gt} = \frac{Q^{gt} - Q^{g(t-1)}}{Q_i^{g(t-1)}}$, the basinwide growth rate for commodity group g.

$$U_i^{gt} = (z_i^{gt} - y^{gt}) O_i^{g(t-1)}$$

where $z_i^{gt} = \frac{O_i^{gt} - O_i^{g(t-1)}}{O_i^{g(t-1)}}$, the growth rate for subarea i for commodity g.

It is the unique growth parameter $z_i^{gt} - y^{gt}$ which we define as u_i^{gt} (excess of commodity specific subareal growth rate over the regionwide commodity specific growth factor) that is calculated for each BEA region, (origins and destinations) for each commodity group, and for each of the seven

iterations covering the years 1969-1976. To arrive at the 1980 u_i^{gt} value, a simple time series regression is performed on the seven historical values. The only other inputs required to obtain the 1980 origin and destination totals are a projected total tonnage figure for 1980 (\hat{Q}^{t*}) and projected tonnages for each commodity group (\hat{Q}_i^{gt}). These projected tonnages are taken from the systemwide projections, the value of which are contained in Section 3 of this report.

Procedures for determining the 1985 u_i^{gt} growth factors are analogous except the 1980 values are added to the original seven historical values and year $t-1$ now refers to the projected 1980 tonnages. Similarly, the 1990 u_i^{gt} values are calculated from nine values (7 observed, 2 projected) and the year $t-1$ refers to the projected 1985 tonnages.

Once the subareal growth estimates ($\Delta O_i^{gt(t-1)}$) have been calculated, they are added to the base year's originating total ($O_i^{g(t-1)}$) to arrive at a future originating total (\hat{O}_i^{gt}).

$$O_i^{gt} = O_i^{g(t-1)} + \Delta O_i^{gt}$$

This is done for each of the n subareas so that we now have an $n \times 1$ vector whose entries consist of the raw projected total shipments for each sub-area. The sum of these entries should be close to Q^{gt} , the projected commodity group tonnage total. In order to obtain a precise match, we calculate a normalizing factor, K , by comparing the desired value, Q^{gt} , with the calculated total tonnage $\sum_{i=1}^n O_i^{gt}$. This should give us a normalizing

factor close to 1.0 by which we multiply each of the O_i^{gt} values, finally arriving at future origination totals for each subarea, the sum of which will equal the projected tonnage for that particular commodity group. The mathematics of the normalizing step is represented as follows:

$$K = \frac{Q^{gt}}{\sum_{i=1}^n O_i^{gt}}$$

$$\hat{O}_i^{gt} = K \cdot O_i^{gt} \text{ for all } i.$$

*"A" notation refers to projected values.

CONSAD initially planned to perform the shift-share analysis at the BEA level rather than at the PE level. This decision was based upon the assumption that the economic behavior of the BEA region mirrors the economic behavior of the areas within the BEA region. This assumption is consistent with the conceptual basis employed in delineating these BEA areas, which relies on central place theory with its emphasis on cities as the focus around and within which integrated economic activity concentrates. Thus, it would seem reasonable to apply the growth factors calculated for a BEA region to its member PE's.

However, in calculating a growth factor, a necessary input is a future originating tonnage total and terminating total for each PE. If Shift-Share is performed at the BEA level, the future BEA tonnage total will have to be apportioned to the member PE's according to the share of the total BEA traffic which each PE had in the base year. However, this allocation procedure presupposes that each PE in a BEA will continue to ship and receive the same proportion of the traffic allotted for that particular BEA.

Another problem associated with BEA level Shift-Share involves BEA 66 (see Figure 4). This economic region contains 20 of the 71 navigation projects under study and a significant portion of the commodity movements both originate and terminate within this region and are intra-BEA 66 movements. BEA level Shift-Share may not be quite sensitive enough to capture the changes in traffic patterns occurring at the PE level which will have an effect on the projected traffic loads assigned to each navigation project.

CONSAD feels that these weaknesses represent only a small source of error, but after examining the historic O-D movement patterns, it was decided that the utilization of the shift-share methodology at the BEA level for Commodity Groups 1 and 4 would be inappropriate (see Appendix D). This decision was made based on both the amount of intra-BEA 66 movement and the fact that these two commodity groups have historically accounted for approximately two-thirds of the total tonnage moving on the waterways of the ORB. Thus, shift-share was applied at the PE level for these two commodity groups, in an attempt to minimize the error associated with assignments of commodity group tonnages to navigation projects.

In actually applying the Shift-Share methodology to the eight years of O-D flow data it was discovered that extrapolation of the unique growth parameters, u_i^{gt} , by simple time series regression was often inappropriate. Since this growth parameter was defined to be the difference between two other growth factors ($z_i^{gt} - y^{gt}$), it should not be too surprising that the u_i^{gt} values often did not show any particular trend. Consequently, unless the time series regression yielded an R^2 value greater than .5, a simple averaging of the historical u_i^{gt} values was used to obtain the 1980, 1985 and 1990 unique growth parameters.

Furthermore, examination of resulting origin and destination totals for 1990 showed that time series regressions of u_i^{gt} sometimes yielded negative u_i^{gt} values, resulting in negative tonnages of shipments. Therefore, the regression procedure was abandoned and the historical u_i^{gt} values were averaged after the smallest and largest were removed so that inordinately large increases or decreases in shipments did not overly effect future shipments.

Having developed the future origin and destination totals, i.e., row and column sums of the future O-D matrices, the next step was to construct the actual matrix cell values representing commodity flows from a particular origin to a particular destination. The Fratar growth factor method is ideally suited for this task.

The basic premise of the Fratar method is that the distribution of future shipments from a zone is proportional to the base year distribution modified by the growth factors of the zones under consideration. This method, as employed by the "PLANPAC / BACKPAC" Urban Transportation Computer Program Package,* applies the origin and destination growth factor to each cell of the O-D matrix in such a way that the future origin total (row sum) is preserved. Actual destination totals (column sums) may not agree with those desired, but an iterative procedure designed to achieve a specified degree of accuracy in the destination totals is included. The mathematical representation of this technique is as follows:

*Computer Programs for Urban Transportation Planning, PLANPAC/BACKPAC General Information, April, 1977, U.S. Department of Transportation, Federal Highway Administration.

$$Q_{ij(k+1)}^{gt} = Q_{ijk}^{g(t-1)} F_{jk} F_{ik}$$

where

$$F_{jk} = \frac{D_j^{gt}}{\sum_{i=1}^n Q_{ijk}^{g(t-1)}}, \quad F_{ik} = \frac{O_i^{gt}}{\sum_{j=1}^n Q_{ijk}^{g(t-1)} F_{jk}}$$

and where

$Q_{ijk}^{g(t-1)}$ = tons shipped between origin i and destination j for iteration k (represents base year tonnage when $k = 1$).

F_{jk} = destination j (column) growth factor.

F_{ik} = origin i (row) growth factor.

D_j^{gt} , O_i^{gt} = projected destination (column) and origin (row) totals obtained from the application of shift-share analysis.

In choosing a commodity specific base year O-D matrix upon which to apply the Fratar growth factor method, it was felt that the most recent O-D matrix (1976) would be most appropriate because its entries would best reflect the shifts in O-D patterns that were occurring over time.* However, given that O-D flows for certain years could represent anomalous behavior and not merely the continuation of some trend, it was decided that the 1976 O-D matrices should be inspected before their use as the base year.

This inspection did not show any extreme shifts in the 1976 O-D matrices relative to the previous years except for Commodity Group 6, where BEA 64 showed a sharp drop in shipments from almost 16 percent

*The base year matrix is used only to provide a pattern of shipments.

of all of commodity group 6 in 1975 to less than 3 percent in 1976. BEA 52 showed a fairly sharp drop in receptions from almost 33 percent to less than 24 percent.

Also, the 1976 total tonnage for Commodity Group 5 seemed high relative to the previous years totals, and it was decided that the 1975 O-D matrix was more appropriate, especially in light of the projections for Commodity Group 5 (see Table 63, Section 3.2 for actual tonnages). Therefore, the 1975 O-D matrix was used as the base year for Commodity Groups 5 and 6, and 1976 was used as the base year for all other commodity groups.

2.4.3 Assignments of Future O-D Movements to Lock and Dam Projects

After developing the 1980, 1985 and 1990 O-D matrix for each commodity group, the remaining task involves taking these O-D flows and assigning the corresponding tonnages to the navigation projects along the river routes which would have to be traversed in going from an origination to a destination. This task falls under the general category of traffic assignment which may be broadly defined as the process of allocating a given set of trip interchanges to a specific transportation system.

The traffic assignment program included in the PLANPAC/BACKPAC computer program package previously mentioned, although usually employed in modeling an urban transportation system, was easily adapted to our purposes. The river system under study can be thought of as a very simple road network, where PE's take the place of intersection's ("nodes" in traffic assignment) and the navigation projects take the place of the roads connecting intersections ("links" in traffic assignment). Once the river network has been described to the computer, i.e., the location of all the PE's and navigation projects in relation to each other and the distances involved, the computer constructs a minimum path tree for all O-D pairs. In the case of the Ohio River System all paths involving O-D pairs are unique except for the section where the Barkley Canal provides an alternate path for traffic involved with the Tennessee or Cumberland and the Ohio Rivers. In that case minimum distance was the criterion

used for choosing the route.* Finally, each commodity specific O-D matrix is input, the tonnage involving each O-D pair is assigned to the navigation projects that would have to be traversed, and the assigned tonnage for each project by commodity group and direction is obtained.

The results of the assignment routine along with graphs for each navigation project depicting historical and projected tonnages in aggregate, appear in Section 3.3.

*This criterion may constitute a departure from the realities of the situation in that other parameters may have equal or greater weight in the choice of an optimum route. The effect on traffic assignment may be some inaccuracy in the allocation of the traffic among the navigation projects in the area - Kentucky L&D (Tennessee River), Barkley L&D (Cumberland River), and the Barkley Canal. However, CONSAD feels that the combined projected total tonnage for these three projects is accurate. The reader should be aware of this potential discrepancy when examining the projections for these projects.

3.0 RESULTS

This section of the report presents the results obtained by the implementation of the analytic techniques described in Section 2 (Analysis) of this report.

3.1 Regression Relationships Obtained

3.1.1 System Level

The equations and associated statistics presented in the tables of this section represent the results of the regression procedures described in Section 2.3.1 of this report.

After the data was aggregated to the system level, it was noticed that commodity group three, crude petroleum, experienced a ten-fold decrease in tonnage between 1972 and 1974. This severe decrease corresponded to the opening of a pipeline between Owensboro and Catlettsburg, Kentucky. In order to ascertain the future picture of crude petroleum barging, an official of the Pipeline Division of the Ashland Oil Company was contacted and interviewed. The Ashland Oil Company is the major shipper of crude petroleum in the ORB area.

We were informed that within three years, all barging of crude petroleum on the rivers of the ORB would cease.* However, until such a time when a new pipeline could be constructed, or the capacity of an existing one increased, barging of crude petroleum from the Gulf coast up the Mississippi and eventually to Owensboro would continue at the approximate rate of 35,000 barrels/day. Given that a barrel of oil weighs about 300 lbs., the annual tonnage of crude petroleum would equal slightly less than two million tons. Therefore, although no further projections of crude

*The future intentions of other shippers will be ascertained during the other projection studies planned by the Corps for the ORB.

petroleum shipments were undertaken, the 1980 upstream tonnages for all lock and dam projects on the Ohio River between Cairo and Owensboro reflect this estimated crude petroleum tonnage.

3.1.2 Individual River Level

The equations presented in the tables of this section represent the results of the procedures described in Section 2.3.2 of this report. Table 15 summarizes the commodity groups studied for each river by direction. Tables 16-36 present the actual equations and associated statistics obtained for each river by direction and commodity group.

Table 15: COMMODITY GROUPS ANALYZED BY RIVER AND DIRECTION

<u>RIVER</u>	<u>DIRECTION</u>	<u>COMMODITY GROUPS ANALYZED</u>

3. 1. 3 Key Lock and Dam Project Level

The equations presented in the tables of this section represent the results of the procedures described in Section 2. 3. 3 of this report. Table 37 lists the key lock and dam projects chosen for analysis, the river on which each is located, and the commodity groups chosen for study. Tables 38-50 present the actual equations and associated statistics obtained for each lock and dam project.

3.1.4 Comparison: System vs. Components

In comparing the regression results obtained using basin level population, income, and earnings as independent variables at the system level versus those obtained at the individual river and key lock and dam levels of analysis, there are several things that the reader must keep in mind. First, in aggregating the river data to create the system data, whatever peculiarities may have been present in each of the individual river data sets would tend to be smoothed out as a result of combining the data on the eight rivers in the ORB. Second, each river flows through an area possessing its own unique industrial and demographic characteristics resulting in river specific commodity mixes as well as the likelihood that these commodities are moving in response to these areal characteristics. Thus, in some cases, it should not be surprising to find sub-system commodity movements correlating poorly with the same variables which produced high correlations at the system level.

Tables 51-58 compare the regression results obtained at the system level versus those obtained for the individual rivers and key lock and dam projects for each commodity group. Except for Commodity Group 8 (Down), a very strong association exists between the Ohio River and the system. This is not at all surprising since the Ohio River has historically carried approximately 75 percent of the system's traffic.

Among the tributaries, the degree of association is not quite as strong, but generally is still significant. However, there are certain exceptions, "weak spots" in the analysis, which require discussion.

For Coal and Coke (Group 1), weak spots occur on the Monongahela (both directions), up the Kanawha, and down the Cumberland, although coal and coke traffic down the Cumberland is relatively light (see Appendix B for river traffic volumes by direction). In all of these cases Earnings in the Manufacture of Primary Metals (XB13) entered the river-level regression equations instead of the variables used at the system level, Earnings in the Manufacture of Chemicals and Allied Products (XB11) and Fabricated Metals (XB14).

For Petroleum Fuels (Group 2) the weak spots occur on the Allegheny and Cumberland Rivers, both directions, although petroleum fuel volume down both of these rivers has been very light. Some preference for Earnings in Petroleum Refining (XB12) was shown over Earnings in Transportation, Communication, and Utilities (XB15), chosen at the system level.

The third major commodity group, Aggregates (Group 4) has weak spots occurring on the Allegheny (both directions), up the Monongahela, and down the Tennessee. Aggregates tonnage moving up the Allegheny dropped quite severly in 1974 and remained low in 1975. Whether or not this represents a permanent drop is a question which can best be answered by the other ORB projection studies being undertaken by the Corps. Earnings in Contract Construction (XB17), used as the independent variable at the system level, entered the equations at the individual river level, except for down the Ohio where Earnings in the Manufacture of Primary Metals (XB13) was entered; up the Allegheny where Earnings in the Manufacture of Primary (XB13) and Fabricated Metals (XB14) were entered; and down the Tennessee where XB14 was again entered.

Grains (Group 5) appear in significant quantities only on the Ohio and Tennessee Rivers. Weak spots exist up the Tennessee and Ohio, although the R^2 and F-test values obtained for these equations were not very different from those obtained for the other grain equations. The variables used at the system level, Earnings in Wholesale and Retail Trade (XB16) and Agriculture (XB06), consistently entered the equations at the individual river level.

For Chemicals and Chemical Fertilizers (Group 6) weak spots occur on the Monongahela and Cumberland Rivers in the downstream direction. However, traffic down the Cumberland for this commodity group has been quite light, reaching a maximum of fifty-three thousand tons in 1973. Except for the Ohio River (other direction) and up the Allegheny, which both correlated best with Earnings in the Manufacture of Chemicals and Allied Products (XB11), the river regression equations utilized the same variables, Earnings in Argiculture (XB06) and Manufacturing (XB09), as the system level equation.

Ores and Minerals (Group 7) has weak spots occurring on the Kanawha (both directions), although traffic volume in the downstream direction is quite light. To a lesser extent, the regression results down the Tennessee, up the Allegheny, and down the Ohio were also weak relative to system level results. Again, however, the traffic volumes are not particularly heavy and variation here is not likely to significantly affect waterway improvement decisions. There was some variation in the variables chosen by the regression package with Earnings in Mining (XB07) and Manufacturing (XB09) carrying about the same load as Earnings in the Manufacture of Primary (XB13) and Fabricated (XB14) Metals, which were utilized at the system level.

The poorest system level regression results were obtained for Iron Ore and Iron and Steel (Group 8) where an R^2 value of .57656 was achieved

using Earnings in Contract Construction (XB17). Significant weaknesses also exist for the subsystem level analysis on the Ohio, Monongahela, Allegheny, and Cumberland Rivers in the downstream direction and on the Kanawha in both directions for this commodity group. However, only the Ohio and Monongahela Rivers transport significant volumes of these materials. There was quite a bit of variation in the entry of independent variables with Earnings in Mining (XB07), Coal Mining (XB08), and the Manufacture of Primary (XB13) and Fabricated (XB14) Metals playing important roles.

The last commodity group, consisting of those commodities not included in the first eight groups, had weak spots occurring on the Allegheny, Kanawha, and Tennessee Rivers in the downstream direction and on the Monongahela in both directions. Only the Tennessee and Monongahela Rivers carried significant traffic volumes. Earnings in Manufacturing, utilized in the system level regression equation for this commodity group was rather consistently chosen at the river level. Notable exceptions are the Ohio (other direction) and up the Tennessee, where in both cases Earnings in Wholesale and Retail Trade was utilized.

In an attempt to improve upon the weak spots identified above, in particular, those involving significant traffic volumes on the Allegheny, Monongahela, and Kanawha Rivers, we turn to the regression results obtained using local variables (Tables 31-36). In several instances local variables yielded much stronger correlations than those obtained using basin level independent variables. Specifically, for Coal and Coke traffic moving up the Monongahela, an R^2 value of .72869 was obtained with Earnings in the Manufacture of Fabricated Metals in BEA region 66 serving as the independent variable. For Aggregates moving up the Allegheny, an R^2 value of .68544 was attained utilizing Earnings in Primary and Fabricated Metals and Contract Construction in BEA region 66. Finally, employing Earnings in Manufacturing in BEA region 66, an R^2 value of .82097 was achieved for commodity group 9, All Other, moving up the Monongahela.

Further inspection of Tables 51-58 brings two general tendencies to light. First, the upstream traffic tends to follow the system's behavior more closely than the downstream traffic. This is especially true for the Allegheny, Monongahela, and Cumberland Rivers. Second, overall results on the Allegheny, Monongahela, and to a lesser extent, the Kanawha were not quite as good (in the sense of mirroring the system's behavior) as those obtained for the other rivers.

At the Key Lock and Dam Level, tests of the system level independent-dependent variable relationships yielded a similar degree of association as was obtained at the individual river level. Although it is difficult to compare the lock and dam results with the river results because the river regressions were made by direction while the lock and dam regressions had to be made in aggregate because of the data problem described in Section 2, one can safely assert that the lock and dam results tended to follow the results for the river on which the lock and dam is located. One exception that immediately stands out occurs on the Ohio River in the case of the Montgomery Lock and Dam Project. Regression results for this project were not nearly as good as those obtained for the Ohio River. A possible explanation lies in this project's location on the Ohio River close to Pittsburgh, where the Allegheny and Monongahela Rivers join to form the Ohio. Since the regression results for the downstream direction of both of these rivers did not follow the high level of correlation obtained at the system level of analysis, the lack of consistency for the Montgomery Locks and Dam are understandable.

Judging from the results of this analysis, it seems reasonable to utilize system level analysis, modified by local trends, to assign future traffic demand to the lock and dam projects in the ORB.

3.2 System Level Demand Projections

In Section 2.3.1 of this report three separate commodity specific regressions of system traffic were described. The first utilized GNP as the independent variable and used all thirty-six years (1940-1975) of commodity data. The other two used fourteen years of data, weighted toward the more recent years, one relying on national level earnings and income independent variables, the other on the same variables at the basin level. The projections obtained as a result of this analysis appear in Tables 60-67.

In applying Shift-Share analysis to arrive at future O-D flows, system-wide total and commodity group tonnage figures for 1980, 1985, and 1990 had to be chosen. Given the above three choices, it was decided that the linear projections based upon fourteen years of data and basin level variables would be most appropriate. Although it could be argued that projections made using thirty-six data points would tend to be more accurate than those based upon fourteen, we felt that since these fourteen points represented the most recent data, they best depicted the current physical characteristics and constraints (lock and dam projects, canals, etc.) of the Ohio River System as well as more recent economic institutional and technological considerations that are inputs to decisions to transport by river barge. The basin level projections were felt to be superior to the national level projections because of the stronger connection present between traffic and the basin's economy. The equations and associated projections selected for use in the Shift-Share procedure appear in Table 59.

It is interesting to note that although the basin level projections differed somewhat from the national level (fourteen points) projections, the total tonnage figures obtained by summing the individual commodity group projections turned out to be remarkably similar. In addition, separate projections of total tonnage with the commodity groups combined were made using national and basin level variables and these values were quite consistent with each other and with the total tonnage projections obtained by summing the individual commodity groups (see Table 68 for details).

Although projections were obtained for Commodity Group 8, the R^2 value for this group was significantly lower than those obtained for the other commodity groups. One possible explanation for this lies in the effect on domestic steel production (and thus on the raw materials, especially iron ore, that serve as inputs to steel production) that has been

**These values were used as the total tonnage projections in the shift-share procedure.

caused by a rapid increase in the imports of steel mill products. The plot of imports of steel mill products and iron ore and iron and steel tonnage on the rivers of the ORB, both versus time (Figure 6), illuminates some interesting patterns. Between 1947 and 1957 when steel imports were low, the tonnage trend was generally upward. However, the rapid increase in imports which began in 1958 and increased rapidly over the next ten years corresponds with a drop and subsequent leveling off of Commodity Group 8 tonnage. It is also interesting to note that sharp increases in imports often correspond to drops in Commodity Group 8 tonnages (1950-1951, 1961, 1962, 1970-1971, 1973-1974) and vice versa (1951-1952, 1971-1972).

Given these patterns, it seem that a fairly strong inverse relationship exists between the imports of steel mill products and the tonnage of Commodity Group 8 moving on the waterways of the ORB. In fact, summing the tonnages of these two variables for each year from 1947 to 1974 and then running a simple time series regression on the resulting series of tonnages yields an R^2 value of .89628. Therefore, although Commodity Group 8 tonnage projections have been made (see Table 59) one should be aware of the fact that this commodity group is very sensitive to the amount of steel mill products imported. Since imports are quite dependent on government policy, a shift in policy regarding imports, could result in a change in Commodity Group 8 tonnage, e.g., an increase in tariffs could cause a decrease in steel mill products imports and a resulting increase in Commodity Group 8 tonnage. Thus, the forecasts of Commodity Group 8 tonnage derived in this study, should be reviewed as government policy in this matter evolves.

Figure 6: Imports of Steel Mill Products and Commodity Group 8
(Iron Ore and Iron and Steel) Tonnages vs. Time

*from Business Statistics, 1975 Biennial Edition

3.3 Assignments of O-D Flows to Rivers and L&D Projects

The tonnages appearing in the 1980, 1985, and 1990 columns of the Tables in this section are the result of running the commodity specific future O-D matrices developed by the Shift-Share and Fratar procedures through the traffic assignment program. The tonnages appearing after "Base Year Assignment" at the bottom of each table result from taking the observed base year flows (1975 for commodity groups 5 and 6, 1976 for the other groups) utilized in the Fratar procedure and running them through the traffic assignment program. This base year assignment was performed mainly as a check to help determine the accuracy of the assignment procedure. By comparing the total tons obtained as a result of the assignment with the observed 1976 tonnage* which also appears on each table, one can see that in most cases the assignment procedure yields results quite close to those actually observed.

It should be noted that the actual O-D matrices at the PE and BEA level of analysis are not included in this report due to the voluminous nature of the material. They are, however, available for review in the Huntington District office of the Corps of Engineers.

*The fact that the base year data included 1975 flows for groups 5 and 6 should not effect the comparison to any great degree since those groups comprise a relatively small portion of total traffic.

4.0 CONCLUSIONS

The methodologies employed by CONSAD in projecting future demand for waterway commodity flows have all utilized historic traffic patterns to predict the future trends. One should realize that changes in either the physical characteristics of the system (e.g., new and/or improved navigation projects) or the competitive relationship between water, rail and pipeline shipping rates, could cause significant changes in the tonnages of commodities moving on the waters of the Ohio River Basin.

In addition, the projected totals for each commodity group depended on the OBERS Series E projections for population, personal income, and earnings of certain key industries. If these projections turn out to be overly optimistic then the commodity group demand forecasts derived from them probably will not be reached.

Overall, the CONSAD analysis projects demand for future system traffic at a little over 328 million tons in 1990. This can be compared with just under 170 million tons of traffic moved in 1975. Table 69 presents total tonnage figures for five-year periods between 1945 and 1975, and the projected values for 1980, 1985, and 1990. Note that the average 5 year percent increase between 1945 and 1975 was 23 percent, quite comparable with the predicted 5-year percent increases between 1975 and 1990.

One might argue that the small increase in total tonnage between 1970 and 1975 represents a slowdown in the growth of waterborne commerce. However, the approximate 5 million ton increase between 1970 and 1975 includes a drop of over 6 million tons of crude petroleum shipments due to the opening of new pipelines. Thus, this special crude petroleum situation partially accounts for the small increase in total tons between 1970 and 1975.

It may well be that the recent apparent slowdown in the rate of increase of river traffic is due to the volume of river traffic approaching the capacity of the river system, i.e., the time required to ship by water may have increased due to the waiting times for use of lock facilities to the point where alternate modes of transport have become more competitive and thus more attractive. It should be noted that CONSAD has developed demand projections, and that capacity constraints were not used in any of

**No crude petroleum

this work except to the extent that historic volumes reflected such constraints. If the capacity of current facilities has been responsible for a slowdown in the rate of increase of waterborne commerce, and continues to be so, one would not expect river traffic to reach the levels estimated in this study without improvement of facilities.

The assignment of commodity group tonnages to individual lock and dam projects was the result of systemwide projected commodity group totals being distributed among the individual originating and receiving ports according to the base year distribution modified by historical trends. This "system to component" approach seems reasonable in light of the analysis in Section 3.1.4 where a fairly strong degree of association was discovered between the system and its components. However, this does not bely the fact that certain commodities are moving in response to very different and/or more localized variables than those that were tested in this study. It is expected that such issues will be addressed in companion ORB traffic projection efforts.

APPENDIX C: Key Lock and Dam Data Set

Note: A zero entry indicates that data was not available for that year, or the lock had not yet opened. It does not necessarily mean that tonnage of that particular commodity group did not move in the year indicated.

APPENDIX E: Commodity Group Definitions

Table E. 1: COMMODITY GROUPINGS TO BE UTILIZED
FOR PROJECTING OHIO RIVER BASIN
WATERWAY TRAFFIC

	<u>COMMODITY GROUP</u>	<u>W. C. S. C.* Commodity Codes</u>
1.	Coal and Coke	1121, 2920, 3313
2.	Petroleum Fuels	2911 thru 2915, 2921
3.	Crude Petroleum	1311
4.	Aggregates	0931, 1411 thru 1442
5.	Grains	0102 thru 0111
6.	Chemical and Chemical Fertilizers	2810 thru 2891
7.	Ores and Minerals	1021 thru 1091, 1451, 1491 thru 1499
8.	Iron Ore and Iron and Steel	1011, 3311, 3314 thru 3319, 4011
9.	All Other	0101, 0112 thru 0913, 1471, 1479 1911 thru 2711, 2916, 2917, 2918, 2951 thru 3291, 3312, 3321 thru 3911, 4012 thru 4113, 4118, 9999

*Waterborne Commerce Statistical Center

Table E. 2: COMMODITY CLASSIFICATION FOR SHIPPING STATISTICS

Note: The commodity descriptions used in the statistical tables in this publication are abbreviated forms—to conserve printing space—of the following commodities.

Code No.	Item Name
Group 01—Farm Products	
0101	Cotton, raw
0102	Barley and rye
0103	Corn
0104	Oats
0105	Rice
0106	Sorghum grains
0107	Wheat
0111	Soybeans
0112	Flaxseed
0119	Oilseeds, not elsewhere classified
0121	Tobacco, leaf
0122	Hay and fodder
0129	Field crops, not elsewhere classified
0131	Fresh fruits and tree nuts, except bananas and plantains
0132	Bananas and plantains
0133	Coffee, green and roasted (including instant)
0134	Cocoa beans
0141	Fresh and frozen vegetables
0151	Live animals (livestock), except zoo animals, cats, dogs, etc.
0161	Animals and animal products, not elsewhere classified
0191	Miscellaneous farm products
Group 08—Forest Products	
0841	Crude rubber and allied gums
0861	Forest products, not elsewhere classified
Group 09—Fresh Fish and Other Marine Products	
0911	Fresh fish, except shellfish
0912	Solefish, except prepared or preserved
0913	Menhaden
0931	Marine shells, unmanufactured
Group 10—Metallic Ores	
1011	Iron ore and concentrates
1021	Copper ore and concentrates
1051	Bauxite and other aluminum ores and concentrates
1061	Manganese ores and concentrates
1091	Nonferrous metal ores and concentrates, not elsewhere classified
Group 11—Coal	
1121	Coal and lignite
Group 13—Crude Petroleum	
1311	Crude petroleum
Group 14—Nonmetallic Minerals, Except Fuels	
1411	Limestone flux and calcareous stone
1412	Building stone, unworked
1442	Sand, gravel and crushed rock
1451	Clay, ceramic and refractory materials
1471	Phosphate rock
1479	Natural fertilizer materials, not elsewhere classified
1491	Salt
1492	Sulphur, dry
1493	Sulphur, liquid
1494	Gypsum, crude and plasters
1499	Nonmetallic minerals, except fuels, not elsewhere classified

Group 19—Ordnance and Accessories	
1911	Ordnance and accessories
Group 20—Food and Kindred Products	
2011	Meat, fresh, chilled, or frozen
2012	Meat and meat products prepared or preserved, including canned meat products
2014	Tallow, animal fats and oils
2015	Animal by-products, not elsewhere classified
2921	Dairy products, except dried milk and cream
2022	Dried milk and cream
2031	Fish and fish products, including shellfish, prepared or preserved
2034	Vegetables and preparations, canned and otherwise prepared and preserved
2039	Fruits and fruit and vegetable juices, canned and otherwise prepared or preserved
* See footnote at end of Commodity Classification.	
2041	Wheat flour and semolina
2042	Prepared animal feeds
2049	Grain mill products, not elsewhere classified
2061	Sugar
2062	Molasses
2081	Alcoholic beverages
2091	Vegetable oils, all grades; margarine and shortening
2092	Animal oils and fats, not elsewhere classified, including marine
2094	Groceries
2095	Ice
2099	Miscellaneous food products
Group 21—Tobacco Products	
2111	Tobacco manufactures
Group 22—Basic Textiles	
2211	Basic textile products, except textile fibers
2212	Textile fibers, not elsewhere classified
Group 23—Apparel and Other Finished Textile Products, Including Knit	
2311	Apparel and other finished textile products, including knit
Group 24—Lumber and Wood Products Except Furniture	
2411	Logs
2412	Rafted logs
2413	Fuel wood, charcoal, and wastes
2414	Timber, posts, poles, piling, and other wood in the rough
2415	Pulpwood, log
2416	Wood chips, staves, moldings, and excelsior
2421	Lumber
2431	Veneer, plywood, and other worked wood
2491	Wood manufactures, not elsewhere classified
Group 25—Furniture and Fixtures	
2511	Furniture and fixtures
Group 26—Pulp, Paper and Allied Products	
2611	Pulp
2621	Standard newsprint paper
2631	Paper and paperboard
2691	Pulp, paper and paperboard products, not elsewhere classified
Group 27—Printed Matter	
2711	Printed matter

Table E. 2: Commodity Classification for Shipping Statistics (continued)

Group 28—Chemicals and Allied Products		Group 33—Continued
2810	Sodium hydroxide (caustic soda)	3321 Nonferrous metals primary smelter products, basic shapes, wire, castings and forgings, except copper, lead, zinc and aluminum
2811	Crude products from coal tar, petroleum, and natural gas, except benzene and toluene	3322 Copper and copper alloys, whether or not refined, unworked
2812	Dyes, organic pigment, dyeing and tanning materials	3323 Lead and zinc including alloys, unworked
2813	Alcohols	3324 Aluminum and aluminum alloys, unworked
2816	Radioactive and associated materials, including wastes	Group 34—Fabricated Metal Products, Except Ordnance, Machinery, and Transportation Equipment
2817	Benzene and toluene, crude and commercially pure	3411 Fabricated metal products, except ordnance, machinery, and transportation equipment
2818	Sulphuric acid	Group 35—Machinery, Except Electrical
2819	Basic chemicals and basic chemical products, not elsewhere classified	3511 Machinery, except electrical
2821	Plastic materials, regenerated cellulose and synthetic resins, including film, sheeting, and laminates	Group 36—Electrical Machinery, Equipment and Supplies
2822	Synthetic rubber	3611 Electrical machinery, equipment and supplies
2823	Synthetic (man-made) fiber	Group 37—Transportation Equipment
2831	Drugs (biological products, medicinal chemicals, botanical products and pharmaceutical preparations)	3711 Motor vehicles, parts and equipment
2841	Soap, detergents, and cleaning preparations: perfumes, cosmetics and other toilet preparations	3721 Aircraft and parts
2851	Paints, varnishes, lacquers, enamels, and allied products	3731 Ships and boats
2861	Gum and wood chemicals	3791 Miscellaneous transportation equipment
2871	Nitrogenous chemical fertilizers, except mixtures	Group 38—Instruments, Photographic and Optical Goods, Watches and Clocks
2872	Potassic chemical fertilizers, except mixtures	3811 Instruments, photographic and optical goods, watches and clocks
2873	Phosphatic chemical fertilizers, except mixtures	Group 39—Miscellaneous Products of Manufacturing
2876	Insecticides, fungicides, pesticides, and disinfectants	3911 Miscellaneous products of manufacturing
2879	Fertilizers and fertilizer materials, not elsewhere classified	Group 40—Waste and Scrap Materials
2891	Miscellaneous chemical products	4011 Iron and steel scrap
Group 29—Petroleum and Coal Products		4012 Nonferrous metal scrap
2911	Gasoline, including natural gasoline	4022 Textile waste, scrap, and sweepings
2912	Jet fuel	4024 Paper waste and scrap
2913	Kerosene	4029 Waste and scrap, not elsewhere classified
2914	Distillate fuel oil	Group 41—Special Items
2915	Residual fuel oil	4111 Water
2916	Lubricating oils and greases	4112 Miscellaneous shipments not identifiable by commodity
2917	Naphtha, mineral spirits, solvents, not elsewhere classified	4113 LCL freight
2918	Asphalt, tar, and pitches	4116 Materials used in waterway improvement, Government materials
2920	Coke, including petroleum coke	9990 "Department of Defense controlled cargo and special category items"
2921	Liquefied petroleum gases, coal gases, natural gas, and natural gas liquids	Statistics on salt in this publication are included with "Nonmetallic minerals, except fuels, not elsewhere classified," commodity code 1499, to avoid disclosure of individual company operations.
2951	Asphalt building materials	"* Cargoes exported on Department of Defense controlled vessels (other than goods for the use of U. S. Armed Forces abroad) and non-Department of Defense shipments of military component items (abbreviated SC) for which commodity detail is not furnished to the Corps of Engineers.
2991	Petroleum and coal products, not elsewhere classified	
Group 30—Rubber and Miscellaneous Plastics Products		
3011	Rubber and miscellaneous plastic products	
Group 31—Leather and Leather Products		
3111	Leather and leather products	
Group 32—Stone, Clay, Glass, and Concrete Products		
3211	Glass and glass products	
3241	Building cement	
3251	Structural clay products, including refractories	
3271	Lime	
3281	Cut stone and stone products	
3291	Miscellaneous nonmetallic mineral products	
Group 33—Primary Metal Products		
3311	Pig iron	
3312	Slag	
3313	Coke (coal and petroleum), petroleum pitches and asphalts, and naphtha and solvents	
3314	Iron and steel ingots, and other primary forms, including blanks for tube and pipe, and sponge iron	
3315	Iron and steel bars, rods, angles, shapes and sections, including sheet piling	
3316	Iron and steel plates and sheets	
3317	Iron and steel pipe and tube	
3318	Ferroalloys	
3319	Primary iron and steel products, not elsewhere classified, including castings in the rough
